# Syntax

# SELECTING ROWS, COLUMNS, AND ITEMS FROM AN NDARRAY

• Convert a list of lists into a ndarray:

```
import numpy as np

f = open("nyc_taxis.csv", "r")

taxi_list = list(csv.reader(f))

taxi = np.array(converted_taxi_list)
```

• Selecting a row from an ndarray:

```
second_row = taxi[1]
```

• Selecting multiple rows from an ndarray:

```
all_but_first_row = taxi[1:]
```

• Selecting a specific item from an ndarray:

```
fifth_row_second_column = taxi[4,1]
```

## SLICING VALUES FROM AN NDARRAY

• Selecting a single column:

```
second_column = taxi[:,1]
```

• Selecting multiple columns:

```
second_third_columns = taxi[:,1:3]
cols = [1,3,5]
second_fourth_sixth_columns = taxi[:, cols]
```

• Selecting a 2D slice:

```
twod_slice = taxi[1:4, :3]
```

#### **VECTOR MATH**

- vector\_a + vector\_b Addition
- vector\_a vector\_b Subtraction
- vector\_a \* vector\_b Multiplication (this is unrelated to the vector multiplication used in linear algebra).
- vector\_a / vector\_b Division
- vector\_a % vector\_b Modulus (find the remainder when vector\_a is divided by
   vector\_b )
- vector\_a \*\* vector\_b Exponent (raise vector\_a to the power of vector\_b )
- vector\_a // vector\_b Floor Division (divide vector\_a by vector\_b , rounding down to the nearest integer)

## CALCULATING STATISTICS FOR 1D NDARRAYS

- ndarray.min() to calculate the minimum value
- ndarray.max() to calculate the maximum value
- ndarray.mean() to calculate the mean average value
- ndarray.sum() \_to calculate the sum of the values

#### CALCULATING STATISTICS FOR 2D NDARRAYS

• Max value for an entire 2D Ndarray:

```
taxi.max()
```

• Max value for each row in a 2D Ndarray (returns a 1D Ndarray):

```
taxi.max(axis=1)
```

• Max value for each column in a 2D Ndarray (returns a 1D Ndarray):

```
taxi.max(axis=0)
```

#### ADDING ROWS AND COLUMNS TO NDARRAYS

• Joining a sequence of arrays:

```
np.concatenate([a1, a2], axis=0)
```

• Expanding the shape of an array:

```
np.expand_dims([1, 2], axis=0)
```

#### SORTING

• Sorting a 1D Ndarray:

```
np.argsort(taxi[0])
```

• Sorting a 2D NDarray by a specific column:

```
sorted_order = np.argsort(taxi[:,15])
taxi_sorted = taxi[sorted_order]
```

# Concepts

- Python is considered a high-level language because we don't have to manually allocate memory or specify how the CPU performs certain operations. A low-level language like C gives us this control and lets us improve specific code performance, but a tradeoff in programmer productivity is made. The NumPy library lets us write code in Python but take advantage of the performance that C offers. One way NumPy makes our code run quickly is **vectorization**, which takes advantage of **Single Instruction Multiple Data (SIMD)** to process data more quickly.
- A list in NumPy is called a 1D Ndarray and a list of lists is called a 2D Ndarray. NumPy ndarrays use indices along both rows and columns and is the primary way we select and slice values.

## Resources

- Arithmetic functions from the NumPy documentation.
- NumPy ndarray documentation
